Saskatchewan Geological Survey

Deep Bay is one of dozens of points of interest on a new map that brings into focus Saskatchewan's geological heritage. Carswell, Deep Bay, and Gow Lake have affected the Canadian Shield area of the north.

Gradually, thick deposits of organic materials accumulated and were buried on the ocean floor.

The age relations of the dikes are not fully understood Stable isotope analyses of the metavolcanic rocks suggest that the original isotopic compositions of these rocks have been reset by progressive metamorphism, perhaps initially involving seawater.

Virtual Saskatchewan

In western Canada, both mass balance and thermodynamic calculations have proved valuable in deciphering many of the intrinsic within-drainage basin processes important in water composition on a local scale e. With such a vast range of salinities, it follows that the concentrations of the individual ionic components also vary greatly. The uraninite is simply zoned and forms clusters, whereas magnetite, the cracks of which are filled by uraninite, occurs as single grains only.

Importantly, the concentrations of Na and SO₄ do not show statistically significant linear correlation, suggesting different suites of processes affect the abundance of each of these ions. They are the remnant of a more widespread , most of which has been removed by erosion.
