Effect of Livestock Grazing on Riparian Stream Ecosystems

With significant socio-economic effects, the physical impacts of projected sea level rise, notably coastal erosion, have received considerable scientific attention Nicholls et al. Modelling vegetation dynamics in heterogeneous pasture-woodland landscapes. Nevertheless, it addressed different aspects related to some types of land degradation in the context of weather and climate extreme events.

Climate change impact and adaptation in agricultural systems

Journal of Range Management 37: 135-139. We show that zooplankton grazing is crucial to explain phytoplankton biomass distributions in this area and conclude that assessments of future distributions should not only consider physical and chemical factors temperature, light, nutrients, pH, but also interactions with other phytoplankton or zooplankton.

Potential role of cryptobiotic soil crusts in semiarid rangelands. Because the regression function also expresses the dependency of productivity on tree cover low forage production of understory in comparison to grassland, the pastoral value of understory was set equal to the value of grassland Table 1.

Livestock grazing and habitat for a threatened species: Land

Noting the limited evidence that exists that explicitly focuses on the relationship between land degradation, climate change and poverty, Barbier and Hochard 2018b suggest that those people living in less-favoured agricultural areas face a poverty—environment trap that can result in increased land degradation under climate change conditions.

This is discussed comprehensively in Chapter 2. Trends in Research in Ecology and Evolution 4: 213-214.
